DUE: THURSDAY NOVEMBER 10, 2016

1. Consider a massive spin-1/2 particle with four-momentum $p^{\mu} = (E; \vec{p})$ and helicity λ (where $2\lambda = \pm 1$). The spin four-vector is defined as:

$$s^{\mu} = \frac{1}{m} \left(\left| \vec{p} \right| ; E \frac{\vec{p}}{\left| \vec{p} \right|} \right) .$$

Verify that $s \cdot p = 0$ and $s \cdot s = -1$.

(a) Show that both the particle and antiparticle helicity spinors $u(p, \lambda)$ and $v(p, \lambda)$ are eigenstates of $\gamma_5 \notin$ with eigenvalue equal to 2λ .

(b) Using the results of part (a), derive the following formulae:

$$u(p,\lambda)\bar{u}(p,\lambda) = \frac{1}{2}(1+2\lambda\gamma_5 s)(p+m),$$

$$v(p,\lambda)\bar{v}(p,\lambda) = \frac{1}{2}(1+2\lambda\gamma_5 s)(p-m).$$

These are called the *helicity spinor projection operators*. Check the above formulae by evaluating both sides of the equations in the rest frame.

HINT: Starting, *e.g.*, with $\sum_{\lambda} u(p,\lambda)\bar{u}(p,\lambda) = \not p + m$, multiply both sides of this equation by a suitable operator that projects out one term in the sum over λ . Using the results of part (a), it should be easy to discover the required operator.

(c) Show that in the high energy limit, $E \gg m$, $s^{\mu} = p^{\mu}/m + \mathcal{O}(m/E)$. Using this result and the result of part (a), show that in the massless limit, $u(p, \lambda)$ and $v(p, \lambda)$ are also eigenstates of γ_5 . What are the corresponding eigenvalues?

(d) Following the limiting procedure of part (c), deduce the helicity spinor projection operators [see part (b)] for the case of massless spin-1/2 particles.

2. For a four-component Dirac field, the transformations

$$\Psi(x) \to \Psi'(x) = \exp(i\alpha\gamma_5)\Psi(x), \qquad \qquad \Psi^{\dagger}(x) \to {\Psi'}^{\dagger}(x) = \Psi^{\dagger}(x)\exp(-i\alpha\gamma_5),$$

where α is an arbitrary real parameter, are called chiral phase transformations.

(a) Show that the Dirac Lagrangian density, $\mathcal{L} = \overline{\Psi}(x)(i\gamma^{\mu}\partial_{\mu} - m)\Psi(x)$, is only invariant under chiral phase transformations in the zero-mass limit, m = 0. Using Noether's theorem, prove that the corresponding conserved current (in the m = 0 limit) is the axial vector current $J^{\mu}_{A}(x) \equiv \overline{\Psi}(x)\gamma^{\mu}\gamma_{5}\Psi(x)$.

(b) Introduce the left-handed and right-handed fields:

$$\Psi_L(x) \equiv \frac{1}{2}(1-\gamma_5)\Psi(x), \qquad \Psi_R(x) \equiv \frac{1}{2}(1+\gamma_5)\Psi(x).$$

Noting that $\Psi(x) = \Psi_L(x) + \Psi_R(x)$, rewrite the Dirac Lagrangian in terms of the two independent fields $\Psi_L(x)$ and $\Psi_R(x)$. Use the hint below to simplify this Lagrangian (by removing any terms that vanish). Starting from the resulting Lagrangian, deduce the (Lagrange) field equations for the left and right-handed fields in the case of nonvanishing mass m, and show that the two field equations decouple in the limit of m = 0.

HINT: Show that $\overline{\Psi}_L \equiv \Psi_L^{\dagger} \gamma^0 = \frac{1}{2} \overline{\Psi} (1 + \gamma_5)$, *etc.* Then, prove that $\overline{\Psi}_L \gamma^{\mu} \Psi_R = 0$ and $\overline{\Psi}_L \Psi_L = 0$, and use these and similar results to simplify your Lagrangian.

(c) Compare the results of part (b) to the Dirac equation in two-component notation. Discuss the relation between the two-component and four-component treatments.

3. In class, we wrote down an expression for the momentum operator P^{μ} in the two cases of a non-interacting scalar and Dirac field theory, respectively. We then inserted the mode expansions for the corresponding quantum fields and obtained P^{μ} as a sum over modes.

(a) Fill in the steps in the case of Dirac field theory; *i.e.*, derive the expression for P^{μ} as a sum over modes $\{\vec{p}, s\}$, where s is the spin quantum number.

(b) Prove that $P^{\mu} |0\rangle = 0$, where $|0\rangle$ is the vacuum state. Interpret the result.

4. In Dirac field theory governed by the Lagrangian $\mathscr{L} = \overline{\Psi}(i\partial \!\!/ - m)\Psi$, the conserved angular momentum tensor operator is given by:

$$J^{\mu\nu} = \int d^3x \,\psi^{\dagger}(x) \left[i(x^{\mu}\partial^{\nu} - x^{\nu}\partial^{\mu}) + \frac{1}{2}\Sigma^{\mu\nu} \right] \psi(x) \,,$$

where $\Sigma^{\mu\nu} \equiv \frac{1}{2}i(\gamma^{\mu}\gamma^{\nu} - \gamma^{\nu}\gamma^{\mu})$ and $\Psi(x)$ is the Dirac (four-component) field operator. As usual, we define the corresponding vector angular momentum and boost operators by $J^i = \frac{1}{2}\epsilon^{ijk}J_{jk}$ and $K^i = J^{0i}$.

(a) Prove that \vec{J} is an hermitian operator.

(b) Derive the following form for \vec{K} :

$$\vec{\boldsymbol{K}} = x^0 \vec{\boldsymbol{P}} - \frac{i}{2} \int d^3 x \, \vec{\boldsymbol{x}} \, \Psi^{\dagger}(x) \overleftrightarrow{\partial}_0 \, \Psi(x) \,, \tag{1}$$

where \vec{P} is the three-vector momentum operator of Dirac field theory and

$$\Psi^{\dagger}(x)\overleftrightarrow{\partial}_{0}\Psi(x) \equiv \Psi^{\dagger}(x)\frac{\partial\Psi(x)}{\partial t} - \frac{\partial\Psi^{\dagger}(x)}{\partial t}\Psi(x) \,.$$

HINT: To derive eq. (1), it is very convenient to make use of the following identity

$$\frac{i}{2} \int d^3x \,\partial_k \left[x^i \,\overline{\Psi}(x) \gamma^k \Psi(x) \right] = 0 \,,$$

which is valid under the assumption that the field $\Psi(x)$ vanishes at spatial infinity. Further simplification can be achieved by noting that $\Psi(x)$ satisfies the free-field Dirac equation.

- (c) Prove that \vec{K} is an hermitian operator.
- (d) Verify that $d\vec{K}/dt = 0$.
- 5. This problem concerns the discrete symmetries P, C and T.

(a) Let $\Phi(x)$ be a complex-valued scalar field previously considered in problem 2 of Problem Set #2. The unitary operators P, C and an antiunitary operator T act on the quantized free complex scalar field as follows,

$$P\Phi(t; \vec{x})P^{-1} = \Phi(t; -\vec{x}),$$

$$C\Phi(t; \vec{x})C^{-1} = \Phi^*(t; \vec{x}),$$

$$T\Phi(t; \vec{x})T^{-1} = \Phi(-t; \vec{x}),$$

where Φ^* is the complex conjugate of the field Φ . Determine the action of P, C and T on the annihilation operators $a_{\vec{p}}$ and $b_{\vec{p}}$ for the charged scalar particles and antiparticles, respectively.

(b) Consider the conserved current operator J^{μ} ,

$$J^{\mu} = i : \left[\Phi^*(\partial^{\mu} \Phi) - (\partial^{\mu} \Phi^*) \Phi \right] :$$

where : \mathcal{O} : indicates that the operator \mathcal{O} is normal ordered. Determine the transformation properties of J^{μ} under P, C and T. Why is the normal ordering in the definition of the operator J^{μ} necessary?

(c) Consider a theory of a charged scalar field $\Phi(x)$ and a Dirac fermion field $\Psi(x)$. Show that any Lorentz invariant hermitian local operator^{*} built from products of $\Phi(x)$, $\Psi(x)$ and their conjugates has CPT = +1.

^{*}By definition, a local operator is a product of fields in which each field is evaluated at the same spacetime point.
